Endogenous and exogenous factors that contribute to the development of osteomalacia have been described. There have been no reports of osteomalacia developing in severe burns. Bone biopsies from 25 burned patients with burns of 30% or more total body surface area were analyzed histologically and histomorphometrically. Ten nonburned controls were used. Demineralization of bone was present in 13 patients (52%). In 7 of these patients the bone resorption was not related to the degree of tissue damage. None of the nonburned controls had bone resorption. Alkaline phosphatase was increased above the normal upper limit in 12 of the a1d647c40b
